BILLS OF MORTALITY 1810-1849

CITY OF BOSTON

INTRODUCTION.

Among the papers preserved in the City Registrar's office, is a volume prepared by Samuel A. Hewes, Superintendent of Burial Grounds. It contains copies of the annual returns of deaths in Boston from 1810 to 1849, at which later date the Registrar's department was established, and the system of more extended annual reports began.

As these old Bills of Mortality are practically inaccessible, being originally published merely as broad-sides, copied for a day into the newspapers, it has seemed desirable to reprint them, on the supposition that statistics of this kind have a value increased by their continuity over considerable periods.

As the volume here printed was the only official copy, though evidently compiled after 1849, it seemed proper to follow its figures despite obvious small errors. The tables have however been collated with the printed copies annually issued and corrections made in the tables of diseases. For more exact comparison reference may be had to the following named publications.

These tables are printed in the Collections of the Massachusetts Historical society as follows:

for 1816 in 2nd Series Vol. VII. pp. 134-5.

Total 904. Note that 10 of the deaths from malignant fever occurred at the Hospital, Rainsford island.

for 1817 in 2nd Series, Vol. VIII. pp. 40-41.

Total 907. Note, there were 5 deaths at Rainsford island, and 173 at the Alms House.

for 1818 in 3rd Series, Vol. I. pp. 278-9.

" 1819 " do do p. 280.

Note, Total 789, to which are added those buried from the Alms House and the town's poor still born 89 pp. 282-3.

do

For the years 1821, 1825, 1836, and 1839–1848 inclusive, copies of the annual broad-side are preserved in this office.

June 25, 1849, the office of City Registrar was created by ordinance and Artemas Simonds was appointed on July 12th. His first report gives the statistics for 1849; and they have been continued for each year since, excepting for the years 1860 and 1861.

For those years the records show the following figures —

```
1860, 5895 births; 2530 marriages; 4390 deaths
1861, 5824 "; 2172 "; 3965 "
1862, 5345 "; 2141 "; 4120 "
```

It should be noted that the figures for 1862 do not agree with the printed report, as births and marriages both continue to be received, recorded and numbered for every year, after the beginning of the next year. The statistics of all the printed reports of this department seem to require this very essential correction. An examination of the State Reports on Registration shows various discrepancies in regard to figures relating to Boston. Perhaps accuracy is not essential in such matters, but the inaccuracies are not systematic.

No comments have been made by me on these Bills of Mortality. Fortunately a very full discussion of the subject was made in 1841 by Lemuel Shattuck, a gentleman of conspicuous ability, whose Report to the City Council on the Census of Boston,' in 1845, placed him at the head of our local statisticians.

As his pamphlet on the Bills of Mortality, covering the period from 1811 to 1841, is seldom obtainable, it has seemed that its reproduction would greatly increase the value of the present volume.

Of course in a literal reprint of Mr. Shattuck's work, there was no room for corrections. But it may be proper to state that since he wrote, in 1841, his comments on the condition of our records, much labor has been expended on the old books. Mr. Apollonio, for so many years City Registrar, caused indexes to be prepared of all the records in his charge. He also did much towards the preservation and arrangement of the old papers which remained in the office. The present Registrar has been directed to prepare consolidated and classified indexes of Boston Births, Marriages and Deaths, and the work is half completed.

Moreover the Record Commissioners, since 1875, have collected transcripts of the records of all the Protestant churches in Boston, established before 1800, and these volumes are now in the Registrar's office. It will be seen that the City of Boston has been ready to avail of all sources to fill up the deplorable gaps in its records of vital statistics. Much remains to be done, and it is hoped that some law will be enacted, authorizing the copying of family records of undoubted authenticity. It seems reasonable to think that the census, taken every five years alternately by the national and state governments, might be utilized so as to allow an official record to be made of all families residing in the city, at least in respect to the births of all persons living here.

I feel it my duty to repeat on every occasion that the births in Boston between 1744 and 1849 are practically lacking. If the persons now living, who were born here prior to 1849, will have the kindness to bring in the evidences before it is too late, they will confer a favor on this office.

W. H. WHITMORE,

City Registrar.

Boston, Oct. 1, 1893.

LEA & BLANCHARD.

1841.

VITAL STATISTICS OF BOSTON.

The oldest book of records of births in Boston was commenced in 1639, and contains some of the marriages, births, and deaths of the previous years, as early as 1630, and of the subsequent years, as late as 1663. This book also contains the births in several towns in Middlesex county, previous to its organization in 1647, and of Suffolk county, then including the present county of Norfolk, until 1663. Another volume embracing the period from 1663 to 1689, appears to have been lost; but a volume containing the records of births only from the earliest entries until 1689, copied from the oldest book, and the one supposed to have been lost, is still preserved. The next volume of records of births extends from 1689 to 1744, the next from 1744 to 1819. The last comprises but few pages. The records appear to have been very irregularly and imperfectly kept after about 1750, and some whole years have recently occurred in which very few records of this kind were made. During the quarter ending Dec. 31, 1838, one birth only was recorded. In some instances the births of one year are placed together in alphabetical order, in others those of several years are placed together in the same manner.

The marriages prior to 1663, were recorded in the oldest book with the births and deaths. From that time to 1689, the records of marriages are lost. Since then they are contained in five volumes. The 1st extends from 1689 to 1720; the 2d from 1720 to 1751; the 3d from 1761 to 1807; the 4th from 1807 to 1828; and the 5th from 1828 to the present time, though not in consecutive, annual order. No records are preserved of the marriages from 1663 to 1689, or from 1751 to 1761, and it is believed that very many

occurred in nearly all the years which have not been recorded. Great carelessness and negligence prevails with some clergymen and magistrates in keeping the records, and in making the returns. The "intentions of marriage" are preserved in twelve volumes, extending from 1707 to the present time. Those from 1818 to 1823, are lost.

The records of *deaths* are made with the births and marriages prior to 1663. From that time until 1689 they are lost. From 1689 to 1719 they are preserved in a separate volume; and from that time till 1810 very few deaths are recorded, and such as are, appear in the volume with the births.

None of these volumes of records, either of births, marriages, or deaths, are provided with indexes; and a search for a fact concerning the personal history of an individual—the only object for which they are valuable—is attended with great labor, and is often fruitless even when the desired fact is recorded. The records are so imperfect, that no general results of any value in statistics, to determine the law of population, or of mortality, could be drawn from any abstract which we could make. It is much to be regretted that our system of registration is such, that we cannot present, in any period of our history, an accurate account of the number of births and marriages. We hope to see a system of registration soon adopted, which will supply all existing deficiencies.*

From 1701 to 1774, the keepers of the several burying-grounds made returns once a week of the number of deaths in Boston, specifying the whites and blacks separately, but not their ages. The number of baptisms was also returned by the several elergymen. Both were published in the newspapers from 1731 to 1774. From these returns an annual statement was compiled and published. We have collected these annual statements, and arranged them with that of the population, in a table, (see Table I,) which exhibits some important information in regard to the health and condition of the town during that period. These returns may be relied on with considerable confidence, as being very nearly correct. The population of Boston was estimated at the beginning of the last century to have been about 6,750, and the annual deaths to be 230 - one in 19.3, or 3.4 per cent. The deaths from 1705 to 1714, inclusive, were 3,341, and from 1715 to 1724, 4,350, giving an annual average of about 1 in 24, or 4.09 per cent. I have estimated the population in the period from 1725 to 1734, according to two enumerations, one taken in 1722, the other in 1735. The eensus was taken in 1742, in 1752, and in 1765, which forms the basis of the estimation in the other periods mentioned. It will be perceived that

^{*} The author of this article has obtained a knowledge of the different systems of registration of births, deaths, and marriages in use in Europe, and he has prepared one which seemed to him best adapted to the institutions of our own country. He has been solicited to bring it before the state legislatures for adoption.

Boston contained more population from 1740 to 1745, than at any other period before the revolution.

Table 1, showing the	rrogress of the population in Boston, for the fifty years from 172 to 1774 divided into periods of 10 years each.	4

Deaths to 100 whole popula-		į				
tion	3.86		3.56	4.26	3.28	3.35
Baptisms to 100 deaths.	129		120	81	93	95

It was customary, at that early period, to baptize nearly all the infants, but toward the last part of the time, embraced in the table, the practice began to be neglected. The returns of baptisms should not, therefore, be taken as a complete return of the births. We made an attempt to obtain the number of marriages, but the records are so imperfect it was abandoned.

It will be perceived, by comparing this table with others directly to be presented, that the mortality in Boston was much higher then than at the present time. The lowest mortality was in 1755 to 1764, being 514—one in 34, or 3.24 per cent. of the population, annually; the highest was in 1745 to 1754, being 671—one in 23, or 4.26 per cent. This is just double the mortality, which prevailed in 1826 to 1835, being then only 2.13 per cent. The lowest mortality in any single year was 407, or 1 in 38, in 1763; the highest 909, or 1 in 14, in 1730, and 1009, or 1 in 15, in 1752.

The mortality of the black, was much greater than that of the white population. In the first period mentioned in the table, it was as low as at any time. One in 18, or 5.64 per cent. of the black population, died, showing a difference of 2.56 per cent., as compared with the mortality of the whites. The highest mortality among the blacks was in 1725 to 1734, being 1 in 12, or 8.64 per cent. These are very striking facts, but are accounted for, in some measure, by the prevalence of the small-pox and other epidemics, which often visited the town at that time, and which seem to have been peculiarly fatal to the black population.

The Small-Pox prevailed in Boston as an epidemic in 1649, 1666, 1678, 1690, and 1702. It is said to have been very fatal in 1678, but we have no particular account of the number of its victims. In 1702, 302 died of this disease, being about 44 per 1000 of the inhabitants. In 1721, the disease broke out with great violence; and 5759 persons (more than half the inhabitants,) had it the natural way, of whom 844, or 1 in 7 died. Inoculation was then, for the first time, introduced, but not without great opposition. Two hundred and forty-seven were inoculated, of whom 6, or 1 in 42 died. Mather, who wrote an account of the epidemic at that time, says that "Cats had a regular small-pox, and died of it;" and that "pigeons and dunghill fowls did not lay nor hatch" during the prevalence of the disorder! In 1730, it has been estimated that 4,000 cases occurred, of which about one-tenth were by inoculation. Of these about 500 died.

In 1752, the disease appeared again in Boston, and became very fatal. The town then contained 15,684 inhabitants; of these 5,998 were supposed to have had the disease. One thousand eight hundred and forty-three removed out of town. All the remainder, except 174, had the disease by inoculation, or the natural way. We have compiled the following statement, to illustrate the prevalence of the disease at this period:—

		Natura	.1.	Inoculated.			
Persons.	Cases.	Deaths.	Ratio per 1000.	Cases.	Deaths.	Ratio*per 1000	
Whites . Black . Both .	5060 485 5545	470 69 539	92 142 97	1985 139 2124	24 6 30	12 43 14	

It appears from this statement, that the liability to death by this disease among the blacks, was about 50 per cent. greater than among the whites, when taken in the natural way; and more than three times as great, when taken by inoculation. The deaths took place in the different months of the year, as follows:—

Month.	Natu	ral.	Inocu	lated.	Total
Month.	Whites.	Blacks.	Whites.	Blacks.	Totai
January	1				1
February	2	_		_	2
March	2	_		_	2
April	20	1	20	6	47
May	205	39	4		248
June	203	20			223
July	31	8	_		39
August	5	1 -	_	-	6
September	1	_	-		1
Total	470	69	24	6	569

In the twenty days, beginning May 19, there were 220 deaths, averaging 10 per day. On the 1st June, 25 took place.

This disease occurred again in 1764, in 1776, in 1778, and in 1792. The following statement exhibits its ravages in the last named period. The town then contained about 18,000 inhabitants, of whom 10,655 were supposed to have had the disease, 262 removed out of town, and 221 only remained unaffected, liable to the disease. The rest had it. The cases by the natural way, and by inoculation, were as follow:—

		Natura	ıl.	Inoculated.			
Persons.	Cases. Deaths.		Ratio per 1000.	Cases.	Deaths.	Ratio per 1000	
White Black	214 18	27 6	125 333	8804 348	157 7	$\begin{array}{c} 17 \\ 20 \end{array}$	
Both	232	33	141	9152	165	18	

The following table exhibits a view of the disease at every period of its appearance in Boston, after 1720:—

			Ratio per 1000 of the population.			Natural	l.	Inoculated.		
Year.	Cases.	Deaths	Sick.	Died.	Cases.	Deaths.	Ratio per 1000	Cases.	Deaths.	Ratio per 1000
1721	6006	850	546	77	5759	844	148	247	6	24
$\frac{1730}{1752}$	$\frac{4000}{7669}$	500 569	$\frac{266}{489}$	33 36	$\frac{3600}{5545}$	488 539	$\frac{135}{97}$	$\frac{400}{2124}$	$\frac{12}{30}$	30 17

			ĺ	İ						

Meastes prevailed in 1713, 1729, 1759, and 1772, and was the cause of many deaths.

In 1745, an epidemic fever occurred of a very fatal character.

The Searlet fever was first introduced into Boston in 1735, and during that and the next year was very prevalent. About 4000 persons were sick with it, of whom 1 in 35 died. At this time it spread generally through the New England towns, carrying off in some instances whole families. In Kingston, where the usual annual mortality was not above 9 or 10, it rose in 1735 to 102, and this great increase of mortality was not unusual in other places. It is somewhat singular, that after the lapse of just about a century, it should have prevailed again as one of the most fatal diseases of New England.

A new system of registration for the deaths only went into operation in Oct. 1810, and has since been continued with some slight modifications. These records are all preserved. At first the town was divided into three districts, the north, middle, and south, and a separate register kept for each,

under the direction of the Board of Health. The particulars recorded were, 1st, The date of death and burial; 2d, The age and sex; 3d, To what family belonging; 4th, The disease, or cause of death; 5th, The number or name of the tomb where interred, designating the burial ground, and whether a eitizen or stranger; and 6th, Remarks. The district system was given up in 1822, at the incorporation of the city, and the office of superintendent of burial grounds was created. This office has since been filled by Mr. Samuel II. Hewes, and he has kept the records of the deaths of the whole city. A "General Abstract of the Bill of Mortality" has been printed annually since 1811, specifying the number of deaths each month in the year, distinguishing the males from the females, and the age under 1; 1 to 2; 2 to 5; 5 to 10; 10 to 20, and each decennial period afterwards to 100. These abstracts specify also the number of deaths by each disease, but not the age, sex, season, and other particulars, which ought to have been noticed. Heavy penalties were imposed for burying without permission; and it is presumed that all, or very nearly all, the deaths that have taken place in the city are recorded. And the "bills," as far as they go, contain a faithful abstract of the records, and may be generally relied on as correct.

Tables of an improved form might have been prepared from the existing records, but to render them as perfect as they ought to be, some modification in the system of keeping the records is necessary. We have compiled from the series of printed abstracts, now before us, several tables, containing important facts and deductions in relation to the vital statistics of Boston. Some others might have been presented had we gone back to the original records, but they would hardly have paid the great labour required for compilation. To render these tables more clearly understood, the condition of the population should be known. We have, therefore, compiled several tables from the different censuses, to illustrate this point.

We have already given an account of the population of Boston previous to 1775. Table II presents the particulars of the population according to the several different enumerations from 1765 to 1830. From this table we have compiled the following abstract, to exhibit the increase of the population:—

Table III, showing the increase of the population at eight enumerations, from 1790 to 1837.

		Actual	Increase.	Increase	per cent.		Square v'rds to
Years.	Population.	Total.	Annual.	Total.	Annual.	One in	each.
1790	18.038						201
1800	24.937	6899	689.9	38.24	3.82	26	145
1810	33.250	8313	831.3	33.33	3.33	30	109
1820	43.298	10048	1004.8	30.22	3.02	33	83
1825	58.281	14983	2996.6	34.60	6.92	14	64
1830	61.392	3111	622.2	5.33	1.06	94	-62
1835	78.603	17211	3442.2	28.03	5.60	17	49
1837	80.325	1722	861.0	2.19	1.09	91	49

From this statement it appears that the greatest increase of the population was from 1820 to 1825, being 14,983, equal to an annual increase of 6.92

per cent., or 1 in 14. The least increase was in 1825 to 1830, being only 1.06 per cent. annually. The whole increase from 1790 to 1837, was 445.3 per cent., or doubling the first mentioned number about 4½ times.

In 1796, Boston, exclusive of South Boston, was estimated to contain 750 acres, or 3,630,000 square yards, including the streets. This may not have been strictly correct, but was an approximation to the truth; and probably the inhabited parts do not now contain more than that quantity of territory. This would give 201 square yards to each inhabitant in 1790, and 49 in 1837, being an increased density of 5 to 1.

Table 1V, showing the population living at each age of the different sexes.

The proportion of living males to living females deserves consideration. There have been in Boston more females than males. The proportion of the aggregate number of each sex of all ages was in 1790, as 100 males to 104.72 females, and in 1800, as 100 to 110.77. The proportion, however, became more equal in 1825, when it was reduced, and was as 100 to-101.96. In 1830, it was as 100 to 111.43. These facts will appear from Table IV, which also shows the census of 1830, and the proportion of each sex living at the different ages. In 1810 there were less females than males living under 10 years. At all other periods under 26 years, excepting 1825, there were more females than males. In the ages 26 to 45, there were more males than females at each enumeration excepting 1800. Above 45 there were from 25 to 70 per cent. more females than males. The most striking difference was in 1820. The proportion of the sexes then changes in the ages 26 to 45; to the ages 45 and upwards, from 81.52 to 171.33 per cent., a difference of 90 per cent. This shows the changeable nature of our population. The ages of 24 to 45 embrace the transient inhabitants — persons in single life, who come here to reside a few years, and afterwards remove. The proportion of population living at all ages will also appear from this

In the census for 1830, we have exhibited the proportion of males to females, and the proportion of both, living at each age; the number surviving, and the proportion per cent. of the surviving at each age; and the proportion of the number surviving each age, that do not attain the next higher age. These deductions are important, as showing the laws of longevity.

The proportion of white to coloured population has been about the same at each of the enumerations, excepting the last two, when the whites had increased, as will appear from the following statement:

Proportion.	In 1790.	In 1800.	In 1810.	In 1820.	In 1825.	In 1830.
Of whites,	95.78	95.30	95.60	95.98	96.71	96.95
Of coloured,	4.22	4.70	4.40	4.02	3.29	3.05
	100.00	100.00	100.00	100.00	100.00	100.00

This shows that in 1790, of the whole population, 95.78 per cent. were white, and the remainder, 4.22, were coloured. In 1830, the proportion of whites had increased, and the coloured decreased, 1.17 per cent.

Table V, showing the influences of the different years on the number of the deaths, distinguishing the males from the females, and the stillborn, and the proportion to the population.

The preceding table, (Table V.) being the first compiled from the printed bills of mortality, presents a general view of the number of deaths each year, from 1811 to 1839, distinguishing the males from the females. The still-born, having never lived, are excluded from the number of deaths in all correct bills of mortality, and are here placed in a separate column. The population at the different enumerations, and the estimated population for the intervening years, and the ratio which the deaths bear to the population, are given. The least mortality in one year was in 1827, being 939, one in 63, or 1.57 per cent., and the greatest in 1821, being 1,321, one in 35, or 2.85 per cent. The average annual deaths were 813, from 1811 to 1830—one in 47, or 2.09 per cent., 1147 from 1821 to 1830—one in 49, or 2.05 per cent., and 1,552 from 1831 to 1839—one in 46, or 2.14 per cent., showing a small increase in the force of mortality.

Mortality of different Ages. — The number of deaths varies very much in the different ages, being in some much greater than in others. We have presented in table VI the number who have died under 1, between 1 and 2, 2 and 5, 5 and 10, and at each subsequent decennial period of life. This has been done for the different sexes, and in the different periods of time — the 10 years, 1811 to 1820, and 1821 to 1830, and the 9 years, 1831 to 1839, that we might institute a comparison between the different periods, to ascertain whether the proportion of deaths was the same in each, and also for the whole 29 years. The greatest number of deaths in any one period mentioned, is under one year, in the period 1831 to 1839, being 2861. The next greatest is between 20 and 30 of the same period, being 1843. The least number is between 90 and 100.

Table VI, showing the influences on the number of deaths in different ages, distinguishing the males from the females, in three different periods of time.

	Age.		Under 5	5 to 10	10 to 20	20 to 30		40 to 50					90 to 100	

In table VII we have given the aggregate number of deaths, and calculated the proportion per cent. of the deaths at each specified interval of age. It appears that 2698, or 33.64 per cent., of the whole deaths in 1811 to 1820 were under 5 years of age, and that 14.13 per cent., the next greatest proportion, was between the ages of 20 and 30. In the next column of this table we have presented the number who survive each specified age, and in the fourth column the proportion per cent. of the surviving. It appears from this table that 5322, or 66.36 per cent., of the deaths in 1811 to 1820 survived the age of 5 years; 1624, or 20.25 per cent., survived the age of 50 years; and 222, or 2.77 per cent., survived the age of 80 years. In the fifth column we have presented the law of mortality calculated from the deaths alone, and given the proportion per cent. of the number of those who were alive at the beginning of each specified age, and who died before the next specified age. Of the whole deaths, 33.64 per cent. were under 5 years; of those who survived 5 years, 5.33 per cent. died before they attained 10 years; of those who survived 10 years, 8.53 per cent. died before they attained 20 years; and so on for each successive period, as appears in the table. We have presented these four different kinds of facts concerning the other periods, 1821 to 1830, and 1831 to 1839. A comparison of these facts presents some very important considerations.

It has been repeatedly said that the great improvements in the science of medicine—in the nature and treatment of disease, and other causes, have increased the average longevity of mankind; that life is more valuable now than it formerly was; and that these improvements are constantly going on. The value of life is estimated by the number of years we live. A long life is more valuable than a short one. It is said to be improved in value, when the various circumstances, which surround us, add to the number of years of existence, as compared with other causes, which have existed in other places or periods of time. No correct conclusion can be made in regard to such comparison, except by a careful examination of the facts. A sufficient number of these is not, however, as yet attainable in this country to enable us to investigate the subject so fully and satisfactorily as could be desired. We can present some important ones in relation to Boston.

By table I we are enabled to compare the ratio of mortality in Boston to the population, during a portion of the last century, with that prevailing at the present time, after an interval of nearly 100 years. There was then I death to about 30 or 35, or 3 per cent., of the population. Now according to table IV there is 1 in about 45, or 2.10 per cent., of the population. This shows a very great improvement in the relative value of life. A comparison of other facts in the two tables will also present some very striking considerations. In consequence of the ages of the deaths not being then given, we are unable to estimate the comparative value of life at the different ages.

To estimate accurately the value of life in any place, two important elements are necessary to be known: first, the number of the living at each age,

and, secondly, the number of deaths at the same age. That we might make a calculation approximating to the truth in regard to Boston, we have taken the population of 1830, according to table II, and have distributed the 1875 blacks among the whites of the different ages according to their respective proportions. From the bills of mortality we have ascertained the number of deaths for the 10 years, 1826 to 1835, five years before and five years after the census was taken, and have distributed the whole, including 126 deaths whose ages were unknown, in the same manner in regard to age as the living. One-tenth of these is the annual average, and consequently the number of deaths for 1830. By dividing one by the other, the annual proportion of the deaths to the living at each age will appear, as in the following statement. We have added the results of a similar calculation made by Mr. Milne, in his valuable treatise on life insurance, respecting the value of life in Carlisle, in England, which is there considered a favourable specimen of healthy life.

Statement showing the population of Boston for 1830, the deaths for 10 years, 1826 to 1835, and the proportion of the annual deaths to 100 constantly living in Boston and Carlisle.

Total	61392	13107			

By this statement it appears that the proportion of deaths to the living is greater in Carlisle than in Boston under the age of 20, and between the ages of 80 and 90. At the other ages it is greater in Boston. Between the ages of 50 and 60, and 90 and 100, there is the greatest difference, being in the former 1.23, and in the latter 2.32. The mean of all ages is 2.13 per cent. in Boston and 2.50 per cent. in Carlisle, showing a difference of .37 in favour of the former. This presents the law of mortality in Boston, as accurately as it could be done from any data at present existing. It is, however, difficult, if not impossible, to determine it with perfect precision by any general statement concerning a population so changeable as that of our city.

We have arranged the tables including the deaths from 1811 to 1839 in such form, that we can institute a comparison between the relative mortality

of the different periods, 1811 to 1820, 1821 to 1830, and 1831 to 1839. This comparison presents some very striking facts, and shows that, although the average value of life is greater now than during the last century, it is not so great as it was twenty years ago; that it was at its maximum in 1811 to 1820, and that it has since somewhat decreased. It appears that 33.64 per cent. of the deaths in 1811 to 1820 were under 5 years of age, 37.04 per cent. in 1821 to 1830, and that 43.09 per cent. in 1831 to 1839, showing a gradual increase of the relative mortality under that age, and between the first and the last given period, a difference of 9.45 per cent. or a proportional increase of mortality of 28 per cent.!

It is a melancholy fact, and one which should arrest the attention of all, that 43 per cent. or nearly half of all the deaths which have taken place in Boston during the last nine years, are of persons under 5 years of age; and the proportional mortality of this age has been increasing. A comparison may be made between other ages by table VII in two ways, one by taking the difference between the proportions per cent. of the dying each age in the different periods, or by subtracting the second columns of each period from each other; and the other by taking the difference between the proportion per cent. of those who survive the first mentioned age, and die before they attain the next age, or by subtracting the fifth columns of each period from each other. The first method is not so correct as the second; for, if a greater proportion die under 5 years of age, there must of course be a less proportion die at each of the other ages, even if the number proportional to the living at that age be the same. It is not so in regard to the other method. The mortality of one age is not dependent on any other, and the table shows the proportion of the whole number of deaths, who attain the age of 5, 10, 20, or any other given period, who die before they attain the next given period. This calculation shows the law of mortality for a place as accurately as can be shown from any calculation from records of deaths alone. We have given below the difference between the proportion per cent. of the deaths at each period. The sign plus shows that the mortality is greater, and minus that it was less in the last period than the first.

It appears from this table that the value of life has slightly improved between the ages 30 and 60 and over 80, the chances being somewhat greater than they were twenty years ago, that a person of these ages will live to the next higher age. Under 30 the mortality has increased; the greatest however is under 5. The mortality for 1838 was greater than in any other year, being 47.65 wanting but 2.35 per cent. of half the whole deaths, showing in that year a greater mortality under 5, than the average eight previous years, of 4.68 per cent., and that of the first ten years of 14.51 per cent.

The causes of this increasing and alarming mortality should be investigated, and, if possible, removed. We have endeavoured to ascertain some of these causes. Allowance should, we suppose, be made for the customs of the times. More luxury and effeminacy in both sexes prevail now than formerly; and this may have had some influence in producing constitutional debility, and the consequent feeble health of children. The nursing and feeding of children with improper food is another cause. The influence of bad air in confined, badly located, and filthy houses, is another and perhaps the greatest. Epidemie diseases which are particularly prevalent among children have increased. It will hereafter be shown that scarlet fever has prevailed very much the last nine years, and has increased the mortality. In the period 1811 to 1820, this disease produced 13 per 1000 of the whole deaths. In 1831 to 1838, it produced 489. Other infantile diseases have also increased. These considerations would, perhaps, sufficiently account for the increased mortality under 5 years of age.

We had supposed that a greater mortality prevailed in certain localities, and in certain classes of our population than in others, and we have endeavoured to ascertain how far the supposition is founded on fact. Though the records do not specify, as they ought, the place of residence of those whose deaths are recorded, they do give, in all cases, the places of burial. We have compiled the following statement from a list of all those, who were buried from Boston in the South Boston and Charlestown Roman Catholic burial grounds.

Of the 1987 Catholic burials during the six years, 1833 to 1838, comprising 1028 males and 958 females, 61.39 per cent. were under 5 years. The still-born during the same time, and in the same religious denomination, not included in the above, were 125, or 5.77 per cent. of the whole burials; 112, or about $5\frac{1}{2}$ per cent. only, lived to see 50 years of age, and 30, or less than 2 per cent. lived to 70. During the year 1838 there were 439 burials; of whom 303, or 171 males and 132 females, were under 5; and 136, or 57 males and 79 females, were over 5. This is a mortality of 75 per cent. of the whole male deaths, and 60 per cent. of the whole female deaths under 5; leaving 25 per cent. only of the males and 40 per cent. of the females, or 31 per cent. of both sexes, to survive that early age. This shows a great increase in mortality, and will account for the increase of the deaths under 5 years of age. The influx of unacclimated foreign emigrants, and the great number of

families crowded into the houses in Broad street, Ann street, and other densely populated parts of the city, render the air very impure, and expose the lives of infants, who are compelled to breathe it, to almost inevitable death. The influences of such circumstances are not confined to the places where they exist, but are extended to the population in the neighbourhood, and epidemies are generated, which are no doubt injurious to the general health of the city.

Mortality of different Sexes. — The difference in the mortality of the two sexes is given in tables V and VI, from which it appears that there were 180 more female than male deaths in 1811 to 1820; 424 in 1821 to 1830, and 341 in 1813 to 1839. There were four years in the first period, and three in the last only, when there were more male than female deaths. The proportion of the different sexes will appear from the following statement.

1811 to 1820 $\begin{cases} \text{Males} \\ \text{Female} \end{cases}$			Proportion. 51.11 48.89	as 100 or 104.59 to 95.66 100.
Total,	8132	813	100.00	
1821 to 1830 $\left\{ \begin{array}{l} \text{Males} \\ \text{Female} \end{array} \right.$	5947 s 5523	$594 \\ 553$	51.85 48.15	as 100 or 107.67 to 92.87 100.
Total,	11470	1147	100.00	
1831 to 1839 { Males Female	7457 s 7116	828 790	51.17 48.83	as 100 or 104.79 to 95.42 100.
Total,	14573	1618	100.00	

The proportion of male and female deaths to the population in the years when the census was taken, was as follows:

		O	ne in		Excess.	I	Proporti	on per cent.		Excess.
1820	Male	s 41	Females	44	3	Males	2.41	Females	2.27	14
1825	4.6	41	+ 6	43	$\overline{2}$	6.6	2.32	"	2.27	5
1830	4.4	54		65	11	6.6	1.83	4 6	1.52	31
1835	4.6	39	4.6	48	9	4.6	2.54	4.6	2.07	47

This statement shows that the agents of death are uniformly more active with male than female life.

In the following table we have given the number of deaths of each sex for the different intervals of age, as in table V, and the proportion of each sex for the period 1811 to 1838.

Age.	Obs	erved.	Calculated.					
age.	Males.	Females.	Males.	Females.				
Under 1	3315	2572	56.31	43.69				
1 to 2	1756	1861	48.54	51.46				
2 to 5	1426	1232	53.65	46.35				
5 to 10	675	537	55.69	44.31				
10 to 20	669	942	41.34	58.66				
20 to 30	2009	2159	48.20	51.80				
30 to 40	2071	1775	53.84	46.16				
40 to 50	1693	1278	56.99	43.01				
50 to 60	1099	915	54.56	45.44				
60 to 70	700	849	45.19	54.81				
70 to 80	521	741	41.28	58.72				
80 to 90	241	376	39.06	60.94				
90 to 100	, 31	83	27.18	72.82				

It appears from this statement, that at the ages under 10 years, and between 30 and 60, more males than females die, the proportion rising in 40 to 50, as 56.99 to 43.01 per cent. At the other periods specified there are less male than female deaths; the difference after the age of 60 continually increasing, until 90 to 100, when it was as 27.18 to 72.82 per cent. By table II it appears that there were a greater number of males than females at any age among the living population. A comparison of these with the deaths will show that at certain ages a greater proportional mortality prevails among males, and at other ages among females.

Mortality of the Different Seasons of the Year. — In table VIII we have arranged the deaths in each period according to the months in which they occurred, distinguishing the males from the females, and placing before the numbers the sign minus, when it was less, and the sign plus, when it was greater than the mean. In the third column we have given the proportion, which the total of each month bears to 12000, or 1000 per mouth, and in the fourth column, the number, indicating the order of the month in regard to mortality — the highest being numbered 1. It appears from this statement, that the months of August, September, and October, have the highest mortality. December is number 4 in each period; November 5 in the last, and 6 in the others. June has uniformly the least mortality. If the proportions are arranged according to the seasons of the year, they will be as follows:

	1811-1820.	1821 - 1830.	1831-1839.
Winter,	2.801	2.775	3.000
Spring,	2.842	2.825	2.622
Summer,	2.807	2.996	2.800
Autumn,	3.550	4.434	4.578
	12,000	12,000	12,000

In table IX, we have endeavoured to arrange the facts for one period, 1821–1830, to ascertain what influence the seasons have upon the mortality of different ages. We have given the whole deaths during the time, the mean or average of each month at each age, and the difference from this mean, placing the sign minus, when the mortality of the month at any age was less, and plus when it was greater, than this mean.

Table IX, showing the influence of the different months of the year on the number of deaths, in the different ages, for the years 1821-1830, inclusive.

From this table the following abstract in relation to the seasons has been compiled.

	Under 20 years.	20 to 60.	60 and upwards.
Spring,	-205.50	+43.75	+3.
Summer,	+ 56.50	+62.75	— 49
Autumn,	+366.50	+70.75	+ 10
Winter,	-222.50	35.75	+52

From this statement it appears that the seasons have the greatest influence on the mortality of persons under the age of 20 and over that of 60—the summer and autumn being most fatal with the former, and winter with the latter. This is the only general law we can deduce from the tables. If we examine and compare particular months and ages a striking difference will appear in the mortality, but not enough to deduce any general law from it.

The Stillborn.—The number and proportion of the stillborn burials will appear from the following statement:

	1811-1820 Number, Proportion.	1821-1830 Number, Proportion,	1831-1839 Number, Proportion.
Deaths, Stillborn,	8,132 = 95.52 471 = 5.48	11,470 = 92.66 909 = 7.34	$ \begin{array}{r} 14,573 = 93.87 \\ 952 = 6.13 \end{array} $
Total burials,	8,603 100.00	${12,379}$ ${100.00}$	${15,525}$ ${100.00}$

The proportion of the stillborn to the whole burials was 1.82 per cent. in the second, and .65 per cent. in the third period, more than in the first. By table VIII it appears that the month producing the highest proportion was August, and that March was the next highest. There appears, however, to be less variation, in regard to the seasons, in these than in the other deaths.

DISEASES.—In compiling an abstract of the diseases, or causes of death, we have confined ourselves to the printed bills of mortality, as we have done in preparing the other tables, and have not gone back to the original records. If this had been done, nothing of great importance, in addition, would have been obtained, unless an entire new set of tables had been formed, which should distinguish each case with respect to age and sex. The records in this respect are not full, and probably they are not always correct in regard to the cause of death inserted. The bills, however, contain the amount of all the deaths in the city, and it is presumed that they also contain a faithful abstract of the records concerning the diseases. There has been considerable difficulty, and great care and labour has been expended, in arranging the diseases from the different annual bills themselves. The nomenclature has been several times altered, and a disease is often returned one year under a name differing from that of the same disease contained in the return of another year, and even in the same year, one and the same disease often appears under two synonymous names, sometimes under the popular, and sometimes under the scientific name, or under both popular names.

Another feature of the bills is the indefinite idea conveyed by the names often given to the diseases. It appears from table XI, that of the whole deaths 111.6, 167.1, and 85.8 per 1000, in the respective period, were returned as occurring from unknown causes, and that 267.6, 160.5, and 158.4, per 1000, from diseases whose seat or character was undetermined. two classes amount on the average to about one-third of the whole deaths. There are also many eases returned under the name of "Rupture," "Debility," "Tumour," "Infantile Diseases," "Complication of Disorders," &c.; and another class under the general name of "Complaint," "Disease of the Heart," or "Disease of the Lungs," &c., without specifying the particular kind or type of the disease. This is a great defect in our records and tables; and it should arrest the attention of the medical profession, whose reputation with that of the city, is in some respects involved in it. These imperfections in bills of mortality, however, are not peculiar to Boston. The same defect, to a greater or less extent, has existed in those published in other places in this country, and until recently in Great Britain. It is to be attributed to the imperfections of our system of registration, to the ignorance, carelessness, or entire neglect, of those whose duty it is to make the returns, and to the want of proper forms and classification of our printed tables.

In 1836 a nomenclature, revised and considerably improved, was printed by the city; but it is believed that some further modification is necessary to make it as perfect as it should be. Some names might be omitted, and others substituted, and the whole arranged in two forms, one in alphabetical and numerical order, the other classed in groups according to the seat of, or parts affected by, the disease. In this way the nomenclature might be rendered more simple and exact; and when made, a form of a return should be prepared and every person concerned should not be requested merely, but required to conform to it in all respects to the extent of his power, and no burial should be permitted until the return is tirst obtained. In 1836 a circular was addressed by the city authorities to the members of the medical profession, and to the funeral undertakers, requesting them to conform to the new nomenclature, but from the fault of one party or the other, the returns relative to the cause of death are still defective.

From these remarks some of the difficulties, which have presented themselves in preparing the following tables, will be perceived. The tables will, however, imperfect as they are, convey much important information, and suggest how much more valuable tables of this kind would have been, if the original returns, from which they were compiled, had been made full and uniformly correct; and the annual printed abstracts themselves prepared in a different form, and on the principles of accurate classification.

It has been considered sufficient by many writers on this subject to prepare the tables, so as to exhibit the number of the deaths by each disease for certain definite periods of time given. But this information appears to fall short of the result which ought to be presented in such tables. To render them useful, a comparison should be made between the number of deaths by each disease, and the whole number of deaths in a certain given period, and this result should be again compared with a similar result concerning other periods. In this way the prevalence of any particular disease compared with that of other diseases at the same period, and with same diseases at different periods, may be at once seen, and a judgment formed from the per centage what proportion of deaths that particular disease occasions, and whether it be on the increase or decrease. The sex, age, and place of nativity of the diseased, and the season of the year in which the deaths occurred, are not stated in connection with the diseases in our printed tables, but they should be. The fatality of disease depends much on the age of the patients, and it is not the same in chilhood, manhood, and old age, nor with the different sexes, and in the different months of the year. It is very important to know all such facts in relation to each disease, and the danger that man has to encounter in all ages, and under all eircumstances. It would also be important, if praeticable, to know the number of deaths by each disease in

proportion to the population, distinguishing them according to their ages. When facts like these are known they will lead to inquiries into the causes, which have produced an increase or diminution of disease, under different circumstances, and lead to the adoption of the proper remedies.

The following tables have been arranged on the basis of the nomenclature contained in the valuable Report of the Registrar-General of Births, Deaths, and Marriages in England, with such alterations as seemed necessary to render them more simple, and better adapted to our circumstances. Causes of death of a similar character, though entered under different names in different years, have been classed together, so as to show, as far as practicable, the prevalence of the same disease during the whole period. Table X contains the number of deaths by each disease in every year from 1811 to 1839 inclusive. They are divided into three periods, the first from 1811 to 1820, the second from 1820 to 1830, and the third from 1830 to 1839 inclusive, and the amount of each given in a separate column. By comparing these numbers together the relative mortality produced by each different disease, and whether it increases or diminishes, may be seen. It is necessary, however, to bear in mind that a greater number does not always indicate an increase of mortality. The increase of the population, and consequent relative increased number of deaths, must always be taken into view. The deaths, exclusive of the stillborn, from October 1810 to 1820, were 8,469, and from 1821 to 1830 they were 11,470, being an increase of 3001, or nearly 3.54 per cent. annually. During the nine last years, from 1831 to 1839, the deaths were 14,573, being an increase of 3,103, or 3 per cent. annually. This shows a little increase in the force of mortality as compared with the increase of population, as has already been shown. Table XI shows the comparison in regard to the several classes of diseases.

First Division.—Endemie, Epidemie, and Contagious Diseases.—This class of diseases is the great index to the state of health of a people, and determines more than any other its character in different locations, and in different periods. We have subdivided this class into fevers, eruptive fevers, and others not classified. (See table X.)

Fevers.—A variety of opinions prevails in regard to the nomenclature and arrangement of the different kinds of fevers. We have adopted, as far as circumstance will permit, the division contained in the American edition of Marshall Hall's Practical Medicine, though it does not agree with the Reports of the Registrar-General of Births and Deaths in England, nor with the Supplement to the Encyclopedia of Practical Medicine. There are many cases, found in the Boston tables, returned as "fever" only, without any specification of kind or type. A great variety of names is also given, some of which have been regarded as synonymous. Under Synochus are included all of a mixed character, or not clearly defined, which appear in the printed tables, such as "fever," "anomalous fever," "bilious," "catarrhal," "country," "isolated," "miliary," "acute synochus," &c. The term "typhoid" does not

appear in the bills until 1837, and is therefore omitted. Under Typhus are included such as "brain," congestive," "continued," "inflammatory," "jail," "malignant," "nervous," "putrid," "typhoid," &c. We have arranged cases, which appeared in the printed tables as "lung fever," and "pleurisy fever," under Pneumonia, or inflammation of the lungs; "worm fever," under Worms; "rheumatic fever," under Rheumatism; "scarlet fever," under Scarlatina; "puerperal" and "child-bed fever," under Diseases of Child-bed. The deaths by fevers of all kinds were 749, 604, and 721, or 88.4, 52.7, and 49.5 per 1000 of the whole deaths in the respective periods, showing a decrease of 35.7 in the second, and 3.2 in the third. By looking at the different fevers in the tables it will be perceived, that typhus has produced the greatest number of deaths, but still it has very much decreased; being 623, 458, and 611, or 73.5, 39.9 and 41.9 per 1000, showing the last eight years a small increase on the previous 10, but not more than half the proportion of the period 1811 to 1820. The greatest number in one year was 119, in 1818. Ten eases of yellow fever occurred in 1816.

- 2. Eruptive Fevers. The diseases of this class occur very irregularly. They have, however, increased. There occurred 64, 402, and 1402, or 7.5, 35.1, and 96.2 per 1000 in the respective periods, the last period showing more than 13 times the mortality of the first. Each of the diseases excepting thrush, shows an increased mortality. Erysipelas has increased from 1, in the first, to 65 in the last period. Measles was very fatal in 1821, 1825, 1829, 1832, and particularly in 1835, when 188 died of this disease: 28, 332, and 340, or 3.3, 28.9, and 23.1 per 1000 of the whole deaths occurred from this disease in the respective periods. Under Scarlatina are included the cases in the bills entered as "searlet fever," "putrid sore throat," "eynanche maligna," "ulcerated sore throat," "throat distemper," "eanker rash," &c., being considered nearly synonymous. Cases of this kind have increased since 1821 to 1830, from 13 to 489! It has become one of the most fatal of the eruptive fevers. The suddenness of its attack, the irregular mode of its operation, and its generally fatal termination, has rendered it one of the diseases most to be dreaded. The greatest number in one year was in 1839, when 222 died. The next greatest was 200 in 1832. To the prevalence of this disease may be attributed, in some measure, the increased mortality of children under five years of age. The recorded eases of Small pox have been principally at the quarantine establishment at Rainsford Island. It never prevailed in the city, as an epidemic, during the period under review, until the autumn of 1839. It then spread generally through the city, and produced 60 deaths before the close of the year.
- 3. Not classified. We have adopted this term to designate such endemie, epidemic, or contagious diseases as are not included in either of the foregoing classes. Under Cholera are included cholera morbus, and also 78, 89, and 251 cases in the respective periods which are entered as "cholera infantum," and also 78 eases of Asiatie or spasmodic cholera, which occurred in 1832. Croup includes the cases of "hives," and "cynanche tra-

chealis." This disease resembles quinsy, subsequently classified under the diseases of the organs of respiration; and the cases may not all be correctly entered in their respective subdivisions. It was thought best, however, to preserve a separate classification. Under *Dysentery* are included the cases of "diarrhea," having so close a resemblance as to be here classed together. The number of deaths by each disease of this class, excepting *Hydrophobia* and *Syphilis*, have increased, though dysentery has not produced so great a proportion in the nine last years, as it did in the previous ten. The following statement will show the comparative prevalence of each of the principal diseases:

	181	1—1820.	1821	-1830.	1831	— 1839.
Diseases.	Number.	Ratio per 1000.	Number.	Ratio per 1000.	Number.	Ratio per 1000.
Cholera,	122	14.4	149	12.9	407	27.9
Croup,	43	5.	245	21.3	376	25.9
Dysentery,	115	13.5	429	37.4	372	25.5
Hoooping Co	ugh, 78	9.2	184	16.0	256	17.5

The total of this class of diseases was 380, 1031, and 1499, or 44.9, 89.9, and 102.9 per 1000 in the respective periods.

Second Division. — Sporadic Diseases.

1. Of the Nervous System and Senses. — Brain, Spinal Marrow, Nerves, Eyes, Ears. - Under Convulsions we include eases entered as "fits," "spasms," &c., which are no doubt sometimes erroneously considered as synonymous terms; under Hydrocephalus cases of "dropsy in the head," "effusion of the brain," "hydrocephalus internus," &c., under Phrenitis cases of "brain fever," "inflammation of the brain," &c. It appears from the tables that the whole of the diseases of this class have been 562, 980, and 1515, or 66.4, 85.4, and 104 per 1000 in the different periods, showing a slight increase. The entries under each class, excepting epilepsy, insanity, and tetanus, also show an increase. Insanity has not appeared to increase, though some allowance should be made for the patients afflicted with this disease, who go to the Lunatic Asylums at Worcester and Charlestown, and sometimes die there. If these were considered in our reports they would probably show a different result, and a slight increase of the disease. The following statement shows the proportional prevalence of the three principal diseases of this class.

	1811	-1820.	1821	— 1830.	183	1—1839.
Diseases.	Number.	Ratio per 1000.	Number.	Ratio per 1000.	Number.	Ratio per 1000.
Apoplexy,	109	12.8	107	9.3	162	11.1
Convulsions,	229	27.	309	26.9	419	28.7
Hydrocephalu	s, 86	10.1	270	23.6	498	34.1

2. Of the Organs of Respiration — Larynx, Windpipe, Air-tubes, Lungs, and Pleura. We have included under Pleurisy "pleurisy fever," "pleuritis," and "inflammation of the pleura;" under Phthisis, "phthisis pulmonalis," and "eonsumption," also 29 eases in 1820 to 1830, and 18 in 1830

to 1839, returned as "decline," under *Pneumonia*, "lung fever," "pulmonie fever," and "inflammation of the lungs," under *Quinsy* "cynanehe." In the different periods under consideration, 2460, 2802, and 3214 deaths, or 290.5, 244.8, and 220.5 per 1000, were caused by this class of diseases. This indicates a decrease of 70 per 1000 from the first to the last period. The following table will show the comparative prevalence of the principal diseases:

	1811	-1820.	1821	-1830.	1831	-1839.
	Number cases.	Ratio per 1000.	Number cases.	Ratio per 1000.	Number cases.	Ratio per 1000.
Pleurisy,	35	4.1	40	3.4	83	5.7
Phthisis,	1891	223.3	2054	179.	2066	141.7
Pneumonia,	436	51.4	580	50.5	937	64.2

The leading disease of this class, and indeed of all classes, is phthisis, or consumption. From these tables it appears to have decreased over onethird from the first to the last period. Entire reliance, however, should not be placed on this statement. There is so much indefiniteness in the application of the term, consumption, as well as many other terms in our bills, that it should be regarded only as an approximation to the truth. The more accurate diagnosis recently observed has probably given a different classifieation to many eases, from that assigned to them in the first period. Consumption is, however, a most formidable disease, not in Boston peculiarly, but in all cities and country towns. Sufficient facts are known to show, that from one-fourth to one-seventh of all the deaths in the Northern and Middle states, and perhaps throughout the whole Union, and the civilized world, are caused by consumption. This frightful mortality is to be arrested, if at all, by means of prevention, rather than the cure of the disease after it has once become seated. Were a competent individual to write a popular treatise explaining the various causes of the disease, and the proper precautionary measures to be taken to prevent its attacks, to be read and observed by the people, its mortality might be greatly reduced.

- 3. Of the Organs of Circulation Heart, Arteries, Veins, Lymphatics.— Under Disease are embraced 9 eases of "dropsy of the heart," in 1836, and several eases of "angina pectoris" in different years. These diseases have increased, being 22, 81, and 191, or 2.5, 7. and 13.1 per 1000. Of the whole of this class, 24, 90, and 200, or 2.9, 7.9, and 13.7 per 1000 occurred in the different periods. It is supposed as the science of medicine progresses, and the diagnosis of disease becomes more perfect, that diseases of the heart will be found to be the cause of more deaths than at present supposed.
- 4. Of the Digestive Organs. Month, Œsophagus, Stomach, &c. Dyspepsia, as a cause of death, appears less frequently in the two last periods than the first. Under Gastritis are included 3 cases of "gastric fever" in 1837; under Disease the cases of "aphtha," "canker," "bowel complaints," and "piles." Canker has sometimes been considered synonymous with searlatina or quinsy, and some cases should probably have been classed

among those diseases. The following statement will show the comparative prevalence of some of the principal diseases of this class:

	1811	-1820.	1821	-1830.	1831	-1839.
	Number cases.	Ratio per 1000.	Number cases.	Ratio per 1000.	Number cases.	Ratio per 1000.
Enteritis,	6	.7	162	14.1	320	21.9
Teething,	39	4.6	83	7.2	247	16.9
Worms,	21	2.5	26	2.2	51	3.5

Most of the other diseases specified have decreased, excepting those of the liver, and the other organs mentioned under the general head, and included under *Disease*. These have greatly increased. The whole number of eases were 231, 644, and 1107, or 27.3, 56.1, and 76, in the different periods.

- 5. Of the Urinary Organs. Kidneys, Ureters, Bladder, Urethra. Under Stone are included all who died of stone or gravel. In the first period there died of this disease 1 in 1411 of all diseases, in the second 1 in 546, and in the third 1 in 2082. Of all the diseases of this class 9, 30, and 22, or 1.1, 2.6, and 1.5 per 1000 occurred in the respective periods.
- 6. Of the Organs of Generation. Under childbed are included cases of "puerperal fever," 63, 121, and 175, or 7.4, 10.5, and 12. per 1000, in the respective periods, occurred by this disease; and 64, 132, and 192, or 7.6, 11.5, and 13.2 per 1000 of the whole deaths of this class.
- 7. Of the Organs of Locomotion.—Under Rhenmatism cases of "rheumatic fever," 20, 40, and 40, have been caused by this disease; and by the whole class 26, 61, and 68, or 3.1, 5.3, and 4.7 per 1000 of the whole deaths.
- 8. Of the Integumentary System. Skin, Cellular Tissue. The deaths by this class were 3, 17, and 26, or .3, 1.5, and 1.8 per 1000 in the respective periods; Ulcers produced the most deaths in this class. "Scurvy" was the cause of 1 death in 1833, and 1 in 1835.
- 9. Of Uncertain seat. The registered deaths by "Infantile Diseases" have been 1587, 883, and 867, or 187.4, 77.9, and 59.4 per 1000 in the respective periods. The "Sudden" Deaths have been 153, 83, and 70, or 18.0, 7.2, and 4.6 per 1000, showing apparently a large decrease in both of these causes of death. A better acquaintance with morbid anatomy, more accurate medical observation, and greater care in making the returns and records, have given more definite character to the eauses of death, and assigned more of them to their proper place. Many cases, which would have been entered in the first period under these names, have in the last been entered under the other and more specific diseases of infaney, or under apoplexy, diseases of the heart, and other causes of "sudden" death. This has apparently decreased the number of eases of infantile diseases and sudden deaths, and increased the number of cases of other diseases in the tables. facts are to be considered in estimating the comparative mortality of the different diseases. The registered deaths by Intemperance have increased, being 65, 257, and 310, or 7, 22.4 and 21.2 per 1000 in the respective periods.

We are inclined to think, however, that the number of deaths by intemperance has not increased so much as the above statement might indicate, but that a different name may have been sometimes given to this cause of death. The cause of the disease, and not the disease itself, may have been entered. An inspection of the table will show great inequalities in the number of entries under different years from other causes. This is especially the case with Atrophy, under which are included the entries by "debility," "decline," "cachexia," "emaciation," "marasmus," &c. Since the laws of sporadic diseases are such, as to produce about the same proportion of deaths in the same population, in specific periods of time, it is certain that these entries cannot be relied on as being accurate causes of death. The whole number by all this class of diseases was 2266, 1841, and 2163, or 267.6, 160.5, and 148.4 per 1000 of the whole deaths, showing considerable improvement in diagnosis, but showing also that much is yet to be done before the tables can be made as accurate as they should be.

- 10. *Old Age*.— The entries under the very indefinite term "*Old age*" were 379, 420, and 581, or 44.8, 36.6, and 39.9 per 1000 in the respective periods. It is worthy of consideration whether many of these cases might not have been entered under some specific disease.
- 11. Deaths by Violence. The greatest number from any single cause of death under this class is by Drowning, the proportion of which has varied, but not increased. The next greatest is inserted under the very indefinite name of Casualties, including all who die from accidental causes. The next are by Burns and Scalds. The deaths by Suicide have stood 29, 50, and 95, or 3.4, 4.3, and 6.5 per 1000 in the respective periods, showing a small increase. Murders have decreased. The whole number by this class are 305, 499, and 611, or 36.0, 43.5, 41.9 per 1000 in the different periods, showing but little variation.
- 12. Unknown Causes.—The tables state the number of deaths, of which the causes are unknown, to have been 945, 1917, and 1251, or 111.6, 167.1, and 85.8 per 1000 in the different periods. This number has varied, and is now considerably decreased in proportion to the whole deaths, but it is still very much greater than it should be. Greater care on the part of the medical profession, and in making the records would reduce it.

From this view of the causes of death in Boston it appears that 1193, 2037, and 3622 cases, or 140.8, 177.7, and 248.6 per 1600 of all the deaths were from epidemic, endemic, and contagious diseases; and that 7275, 9433, and 10,951 cases, or 859.2, 822.3, and 751.4 per 1000 of all the deaths were from sporadic diseases. This shows an increase of the first, and a decrease of the second division of diseases, in the respective periods. If, as has been stated, the great criterion of health is the comparative prevalence of one or the other of these two great divisions of diseases, it follows that Boston is not now quite as healthy as it was twenty or thirty years ago. This fact, I think, may be inferred also from other investigations given in this article.

Table X, showing the number of deaths in Boston

Table XI, showing the number of deaths, and the ratio per 1000 by each class of diseases, in the three periods, 1811-1820, 1821-1830, and 1831-1839.

This article has already extended so far that the author is induced to omit all comparisons between Boston and other places, in regard to the prevalence of particular diseases, or the general mortality. He has a series of the bills of mortality of the principal cities in the United States, and a great mass of similar facts from Europe, which he reserves for a future consideration.

Since the foregoing article was in the hands of the printer the population of Boston, and the bill of mortality for 1840 have been obtained; and it is deemed expedient to annex the following abstract of these documents.

A census was taken by authority of the state, on the first day of May, for the purpose of an apportionment of the representatives in the legislature, which excluded some classes of the inhabitants. According to the census of the United States the whole population was 93,470, whites 91,188, or 97.55 per cent., and coloured 2321, or 2.55 per cent. Of these 10,805 were returned as engaged in navigation, a large portion of whom, being constantly absent, should not be embraced in the comparative estimates of the deaths to the living. The white population, among whom the recorded deaths occur, may be estimated at 84,311, and the coloured at 2321. The deaths in 1840, exclusive of the stillborn, were 1841 whites, or 1 in 47, or 2.10 per cent. and 64 coloured, or 1 in 36, or 2.75 per cent. being about the average for the

previous years. The whites were distributed according to ages, as in the following table. The male deaths were 951, and the female 890. There were 45 more males than females died under five years of age.

Disease.—Of 533 deaths caused by endemic, epidemic, [and contagious diseases, 97 were from fevers, 202 from eruptive fevers, and 234 from others not classified. Of these 89 were by typhus fever, 76 by scarlatina, 116 by small pox, 55 by cholera, 58 by dysentery, and 70 by whooping cough, showing, by comparing it with Table X, an increased prevalence of some diseases, and a decrease of others.

Of the 1308 deaths caused by sporadic diseases, 200 were by diseases of the nervous system, 402 of the organs of respiration, 18 of the organs of circulation, 126 of the organs of digestion, 1 of the urinary organs, 24 of the organs of generation, 8 of the organs of locomotion, 5 of the integumentary system, 295 of uncertain seat, 64 of old age, 79 by violence, and 86 by unknown causes. The stillborn were 131. This shows no peculiar feature in the prevalence of these diseases, when compared with the prevalence of the same diseases for the previous nine years.

DEATH RETURNS FROM 1810 TO 1850.

APPENDIX A.

As there may be some value in comparisons based on these statistics, it seems proper to show the exact figures of Boston Births, Marriages, and Deaths, in contrast with those heretofore given out. I submit therefore the following tables from 1849 to to 1892, with explanations:

Birtus.

The births in Boston were all collected annually in January by persons employed under a contract. These returns were received about March or April, and were sent to the State authorities by May. The City Registrar's reports were prepared from the same data as those printed in the Secretary's report for the whole Commonwealth, and a close correspondence between them was to be expected. But in every year returns continued to be made, so that the Registrar's books contain now more births than appear in those reports. The true returns give about two per cent. more in many years, but the percentage is not constant.

Deaths.

As the deaths are necessarily reported and recorded day by day, the agreement between the record and the reports should be very close. Of course one or two returns may come in after January, but it will be seen that the Registrar's printed reports are often exactly right. The Secretary's reports differ slightly, showing the impossibility of perfect uniformity in returns made by different authorities from the same data.

MARRIAGES.

Under this head the greatest discrepancies will naturally be found. When the license is given out, no time can be set for its return. The parties may defer marriage for months or years, and the minister or justice may be delinquent in returning the certificate after marriage. In many cases the delay has exceeded a year. I cannot explain the reason for the fact that prior to 1879 the Secretary's report usually gives less marriages than the Regis-

trar's report does. The correct figures are sufficiently larger to make all statistics of very doubtful value.

It will be noted that from 1879 to 4891 the City Registrar's reports give many more marriages than are on the city record or in the Secretary's reports. It is almost beyond doubt that in 1879 the Registrar incorporated into the total of his marriages not only those celebrated in this city, but the return from other cities and towns in this State, where one party belonged in Boston. We have in this office two volumes of such marriages, and the following facts may be of use. The records of these marriages show as follows:

1854	to 1	867	290	1875		230	1884		452
1867			195	1876		198	1885		456
1868			164	1877		211	1886		551
1869			187	1878		234	1887		539
1870			209	1879		262	1888		578
1871			244	1880		331	1889		594
1872			280	1881		388	1890		617
1873			249	1882		440	1891		595
1874			244	1883		430	1892		681
				l			1		

It seems also that marriages of Bostonians, solemnized out of the Commonwealth, have usually been recorded and numbered among the marriages performed in the city. From one point of view this is incorrect, and yet such data are not only required by law, but are of interest. It is beyond question that most of such marriages are not reported, however, and the penalty inflicted by the present law is very slight. There seems to be no reason why the notice should not be given and the certificate issued in advance in all these cases of intended foreign marriages.

W. H. WHITMORE.
